

IN THE CLAIMS:

1. (Currently Amended) A driver circuit for driving a permanent-magnet electric motor, comprising:

an inverter for generating an electric current to be applied to the permanent-magnet motor, according to a commanded voltage value applied thereto;

a motor-drive-current detector operable to detect the drive current of the motor;

a current detector operable to detect a d-axis current and a q-axis current which are respectively an exciting current component and a torque current component of the detected drive current; and

a controller operable to calculate a d-axis current difference between the detected d-axis current and a commanded d-axis current value, and a q-axis current difference between the detected q-axis current and a commanded q-axis current value, said controller being further operable to calculate a d-axis difference signal which is a function of a d-axis input voltage of the motor and is not a function of a q-axis input voltage of the motor, and a q-axis difference signal which is a function of the q-axis input voltage and is not a function of the d-axis input voltage, said controller controlling said inverter on the basis of the calculated d-axis and q-axis difference signals, such that the d-axis and q-axis difference signals are zeroed, wherein said controller generates a value xd as said d-axis difference signal, and a value xq as said q-axis difference signal, based on factors including an inductance of the motor and an electric resistance of the motor.

2. (Currently Amended) A driver circuit according to claim 1, wherein said factors further include an angular velocity of the motor. [[said controller generates a value xd as said d-axis difference signal, and a value xq as said q-axis difference signal, the values xd and xq being represented by the following equation:

$$\begin{pmatrix} xd \\ xq \end{pmatrix} = \begin{pmatrix} R - \omega L_d & -\omega L_q \\ \omega L_d & R - \omega L_q \end{pmatrix} \begin{pmatrix} jd \\ jq \end{pmatrix} + \begin{pmatrix} \omega L_d & 0 \\ 0 & \omega L_q \end{pmatrix} \begin{pmatrix} idr - id \\ iqr - iq \end{pmatrix}$$
$$\frac{d}{dt} \begin{pmatrix} jd \\ jq \end{pmatrix} = \begin{pmatrix} -\omega L & 0 \\ 0 & -\omega L \end{pmatrix} \begin{pmatrix} jd \\ jq \end{pmatrix} + \begin{pmatrix} \omega L & 0 \\ 0 & \omega L \end{pmatrix} \begin{pmatrix} idr - id \\ iqr - iq \end{pmatrix}$$

wherein id is said d-axis current,

iq is said q-axis current,

idr is said commanded d-axis current value,
iqr is said commanded q-axis current value,
vd is a d-axis voltage applied to the motor,
vq is a q-axis voltage applied to the motor,
Ld is an inductance of the d-axis of the motor,
Lq is an inductance of the q-axis of the motor,
R is an electric resistance of the motor,
 ω is an angular velocity of a rotor of the motor,
 Φ is a number of magnetic cross fluxes of a permanent magnet of the motor,
jd is a d-axis state quantity of said controller,
jq is a q-axis state quantity of said controller, and
 ω_d is a coefficient.]]

3. (Currently Amended) A driver circuit ~~according to claim 1~~ for driving a permanent-magnet electric motor, comprising:

an inverter for generating an electric current to be applied to the permanent-magnet motor, according to a commanded voltage value applied thereto;

a motor-drive-current detector operable to detect the drive current of the motor;

a current detector operable to detect a d-axis current and a q-axis current which are respectively an exciting current component and a torque current component of the detected drive current; and

a controller operable to calculate a d-axis current difference between the detected d-axis current and a commanded d-axis current value, and a q-axis current difference between the detected q-axis current and a commanded q-axis current value, said controller being further operable to calculate a d-axis difference signal which is a function of a d-axis input voltage of the motor and is not a function of a q-axis input voltage of the motor, and a q-axis difference signal which is a function of the q-axis input voltage and is not a function of the d-axis input voltage, said controller controlling said inverter on the basis of the calculated d-axis and q-axis difference signals, such that the d-axis and q-axis difference signals are zeroed, wherein said controller is operable for calculating said d-axis difference signal and said q-axis difference signal in a low frequency range, said controller controlling said inverter on the basis of the calculated d-axis and q-axis difference signals, such that the d-axis

and q-axis difference signals are zeroed, and said controller generates a value x_d as said d-axis difference signal, and a value x_q as said q-axis difference signal, the values x_d and x_q being represented by the following equation:

$$\begin{pmatrix} x_d \\ x_q \end{pmatrix} = \begin{pmatrix} R & \omega L_q \\ -\omega L_d & R \end{pmatrix} \begin{pmatrix} i_{dr} - i_d \\ i_{qr} - i_q \end{pmatrix}$$

wherein i_d is said d-axis current,

i_q is said q-axis current,

i_{dr} is said commanded d-axis current value,

i_{qr} is said commanded q-axis current value,

L_d is an inductance of the d-axis of the motor,

L_q is an inductance of the q-axis of the motor,

R is an electric resistance of the motor, and

ω is an angular velocity of a rotor of the motor.

4. (Canceled)

5. (Currently Amended) A driver circuit for driving a permanent-magnet electric motor, by comprising:

an inverter for generating an electric current to be applied to the motor, according to a commanded voltage value applied thereto;

a motor-drive-current detector operable to detect a drive current of the motor;

a current detector operable to detect a d-axis current and a q-axis current which are respectively an exciting current component and a torque current component of the detected drive current;

a current-difference calculator operable to calculate a d-axis current difference between the detected d-axis current and a commanded d-axis current value, and a q-axis current difference between the detected q-axis current and a commanded q-axis current value;

a non-interference processor operable to calculate a d-axis difference signal which is a function of a d-axis input voltage of the motor and is not a function of a q-axis input voltage of the motor, and a q-axis difference signal which is a function of the q-axis input voltage and is not a function of the d-axis input voltage; and

an inverter controller operable to control said inverter on the basis of the calculated d-axis and q-axis difference signals, such that the d-axis and q-axis difference signals are zeroed,

wherein that said non-interference processor generates a value x_d as said d-axis difference signal, and a value x_q as said q-axis difference signal, the values x_d and x_q being represented by the following equation:

$$\begin{pmatrix} x_d \\ x_q \end{pmatrix} = \begin{pmatrix} R - \omega L_d & -\omega L_q \\ \omega L_d & R - \omega L_q \end{pmatrix} \begin{pmatrix} j_d \\ j_q \end{pmatrix} + \begin{pmatrix} \omega L_d & 0 \\ 0 & \omega L_q \end{pmatrix} \begin{pmatrix} i_{dr} - i_d \\ i_{qr} - i_q \end{pmatrix}$$

$$\frac{d}{dt} \begin{pmatrix} j_d \\ j_q \end{pmatrix} = \begin{pmatrix} -\omega & 0 \\ 0 & -\omega \end{pmatrix} \begin{pmatrix} j_d \\ j_q \end{pmatrix} + \begin{pmatrix} \omega & 0 \\ 0 & \omega \end{pmatrix} \begin{pmatrix} i_{dr} - i_d \\ i_{qr} - i_q \end{pmatrix}$$

wherein i_d is said d-axis current,

i_q is said q-axis current,

i_{dr} is said commanded d-axis current value,

i_{qr} is said commanded q-axis current value,

v_d is a d-axis voltage applied to the motor,

v_q is a q-axis voltage applied to the motor,

L_d is an inductance of the d-axis of the motor,

L_q is an inductance of the q-axis of the motor,

R is an electric resistance of the motor,

ω is an angular velocity of a rotor of the motor,

Φ is a number of magnetic cross fluxes of the permanent magnet,

j_d is a d-axis state quantity of said non-interference processor,

j_q is a q-axis state quantity of said non-interference processor, and

ω_d is a coefficient.

6. (Canceled)

7. (Currently Amended) A driver circuit according to claim [6] 5, wherein that said non-interference processor is operable on the basis of the calculated d-axis and q-axis current differences, for calculating said d-axis difference signal and said q-axis difference signal in a low frequency range.

8. (Currently Amended) ~~A driver circuit according to claim 7~~ A driver circuit for driving a permanent-magnet electric motor, by comprising:

an inverter for generating an electric current to be applied to the motor, according to a commanded voltage value applied thereto;

a motor-drive-current detector operable to detect a drive current of the motor;

a current detector operable to detect a d-axis current and a q-axis current which are respectively an exciting current component and a torque current component of the detected drive current;

a current-difference calculator operable to calculate a d-axis current difference between the detected d-axis current and a commanded d-axis current value, and a q-axis current difference between the detected q-axis current and a commanded q-axis current value;

a non-interference processor operable to calculate a d-axis difference signal which is a function of a d-axis input voltage of the motor and is not a function of a q-axis input voltage of the motor, and a q-axis difference signal which is a function of the q-axis input voltage and is not a function of the d-axis input voltage; and

an inverter controller operable to control said inverter on the basis of the calculated d-axis and q-axis difference signals, such that the d-axis and q-axis difference signals are zeroed, wherein that said non-interference processor generates a value x_d as said d-axis difference signal, and a value x_q as said q-axis difference signal, the values x_d and x_q being represented by the following equation:

$$\begin{pmatrix} x_d \\ x_q \end{pmatrix} = \begin{pmatrix} R & \omega L_q \\ -\omega L_d & R \end{pmatrix} \begin{pmatrix} i_{dr} - i_d \\ i_{qr} - i_q \end{pmatrix}$$

wherein i_d is said d-axis current,

i_q is said q-axis current,

i_{dr} is said commanded d-axis current value, i_{qr} is said commanded q-axis current value,

L_d is an inductance of the d-axis of the motor,

L_q is an inductance of the q-axis of the motor,
 R is an electric resistance of the motor,
 ω is an angular velocity of a rotor of the motor.

9. (Currently Amended) A driver circuit for driving a permanent-magnet electric motor, comprising:

an inverter for generating an electric current to be applied to the permanent-magnet motor, according to a commanded voltage value applied thereto;

motor-drive-current detecting means for detecting the drive current of the motor;

current detecting means for detecting a d-axis current and a q-axis current which are respectively an exciting current component and a torque current component of the detected drive current;

current-difference calculating means for calculating a d-axis current difference between the detected d-axis current and a commanded d-axis current value, and a q-axis current difference between the detected q-axis current and a commanded q-axis current value;

non-interference processing means for calculating a d-axis difference signal which is a function of a d-axis input voltage of the motor and is not a function of a q-axis input voltage of the motor, and a q-axis difference signal which is a function of the q-axis input voltage and is not a function of the d-axis input voltage; and

inverter control means for controlling said inverter on the basis of the calculated d-axis and q-axis difference signals, such that the d-axis and q-axis difference signals are zeroed, wherein that said non-interference processing means generates a value x_d as said d-axis difference signal, and a value x_q as said q-axis difference signal, the values x_d and x_q being represented by the following equation:

$$\begin{pmatrix} x_d \\ x_q \end{pmatrix} = \begin{pmatrix} R & \omega L_q \\ -\omega L_d & R \end{pmatrix} \begin{pmatrix} i_{dr} - i_d \\ i_{qr} - i_q \end{pmatrix}$$

wherein i_d is said d-axis current,

i_q is said q-axis current,

i_{dr} is said commanded d-axis current value, i_{qr} is said commanded q-axis current value,

L_d is an inductance of the d-axis of the motor,

L_q is an inductance of the q-axis of the motor,

R is an electric resistance of the motor,

ω is an angular velocity of a rotor of the motor.

10. (Currently Amended) A method of controlling a driver circuit for driving an electric motor, ~~characterized by~~ comprising the steps of:

detecting a drive current of the motor;

detecting a d-axis current and a q-axis current which are respectively an exciting current component and a torque current component of the detected drive current;

calculating a d-axis current difference between the detected d-axis current and a commanded d-axis current value, and a q-axis current difference between the detected q-axis current and a commanded q-axis current value;

calculating a d-axis difference signal which is a function of a d-axis input voltage of the motor and is not a function of a q-axis input voltage of the motor and a q-axis difference signal which is a function of the q-axis input voltage and is not a function of the d-axis input voltage; and

controlling an inverter on the basis of the calculated d-axis and q-axis difference signals, such that the d-axis and q-axis difference signals are zeroed, wherein said step of calculating a d-axis difference signal and a q-axis difference signal comprises calculating a value x_d as said d-axis difference signal, and a value x_q as said q-axis difference signal, according to the following equation:

$$\begin{pmatrix} x_d \\ x_q \end{pmatrix} = \begin{pmatrix} R - \omega L_d & -\omega L_q \\ \omega L_d & R - \omega L_q \end{pmatrix} \begin{pmatrix} j_d \\ j_q \end{pmatrix} + \begin{pmatrix} \omega L_d & 0 \\ 0 & \omega L_q \end{pmatrix} \begin{pmatrix} i_{dr} - i_d \\ i_{qr} - i_q \end{pmatrix}$$

$$\frac{d}{dt} \begin{pmatrix} j_d \\ j_q \end{pmatrix} = \begin{pmatrix} -\omega & 0 \\ 0 & -\omega \end{pmatrix} \begin{pmatrix} j_d \\ j_q \end{pmatrix} + \begin{pmatrix} \omega & 0 \\ 0 & \omega \end{pmatrix} \begin{pmatrix} i_{dr} - i_d \\ i_{qr} - i_q \end{pmatrix}$$

wherein i_d is said d-axis current,

i_q is said q-axis current,

i_{dr} is said commanded d-axis current value,

i_{qr} is said commanded q-axis current value,

v_d is a d-axis voltage (actually applied to the motor),

v_q is a q-axis voltage (actually applied to the motor),

L_d is an inductance of the d-axis of the motor,

L_q is an inductance of the q-axis of the motor,

R is an electric resistance of the motor,
 ω is an angular velocity of a rotor of the motor,
 Φ is a number of magnetic cross fluxes of the permanent magnet,
 j_d is a d-axis state quantity,
 j_q is a q-axis state quantity, and
 ω_d is a coefficient.

11. (Canceled)

12. (Previously Presented) A method according to claim 10, wherein said step of calculating a d-axis difference signal and a q-axis difference signal comprises calculating, on the basis of the calculated d-axis and q-axis current differences, said d-axis difference signal and said q-axis difference signal in a low frequency range.

13. (Currently Amended) ~~A method according to claim 12~~ A method of controlling a driver circuit for driving an electric motor, comprising the steps of:

detecting a drive current of the motor;
detecting a d-axis current and a q-axis current which are respectively an exciting current component and a torque current component of the detected drive current;
calculating a d-axis current difference between the detected d-axis current and a commanded d-axis current value, and a q-axis current difference between the detected q-axis current and a commanded q-axis current value;
calculating a d-axis difference signal which is a function of a d-axis input voltage of the motor and is not a function of a q-axis input voltage of the motor and a q-axis difference signal which is a function of the q-axis input voltage and is not a function of the d-axis input voltage; and
controlling an inverter on the basis of the calculated d-axis and q-axis difference signals, such that the d-axis and q-axis difference signals are zeroed, wherein said step of calculating a d-axis difference signal and a q-axis difference signal comprises calculating a value x_d as said d-axis difference signal, and a value x_q as said q-axis difference signal, according to the following equation:

$$\begin{pmatrix} x_d \\ x_q \end{pmatrix} = \begin{pmatrix} R & \omega L_q \\ -\omega L_d & R \end{pmatrix} \begin{pmatrix} i_{dr} - i_d \\ i_{qr} - i_q \end{pmatrix}$$

wherein i_d is said d-axis current,

i_q is said q-axis current,

i_{dr} is said commanded d-axis current value,

i_{qr} is said commanded q-axis current value,

L_d is an inductance of the d-axis of the motor,

L_q is an inductance of the q-axis of the motor,

R is an electric resistance of the motor, and

ω is an angular velocity of a rotor of the motor.

14. (New) A driver circuit according to claim 2, wherein the values x_d and x_q being represented by the following equation:

$$\begin{pmatrix} x_d \\ x_q \end{pmatrix} = \begin{pmatrix} R - \omega L_d & -\omega L_q \\ \omega L_d & R - \omega L_q \end{pmatrix} \begin{pmatrix} j_d \\ j_q \end{pmatrix} + \begin{pmatrix} \omega L_d & 0 \\ 0 & \omega L_q \end{pmatrix} \begin{pmatrix} i_{dr} - i_d \\ i_{qr} - i_q \end{pmatrix}$$

$$\frac{d}{dt} \begin{pmatrix} j_d \\ j_q \end{pmatrix} = \begin{pmatrix} -\omega d & 0 \\ 0 & -\omega d \end{pmatrix} \begin{pmatrix} j_d \\ j_q \end{pmatrix} + \begin{pmatrix} \omega d & 0 \\ 0 & \omega d \end{pmatrix} \begin{pmatrix} i_{dr} - i_d \\ i_{qr} - i_q \end{pmatrix}$$

wherein i_d is said d-axis current,

i_q is said q-axis current,

i_{dr} is said commanded d-axis current value,

i_{qr} is said commanded q-axis current value,

v_d is a d-axis voltage applied to the motor,

v_q is a q-axis voltage applied to the motor,

L_d is an inductance of the d-axis of the motor,

L_q is an inductance of the q-axis of the motor,

R is an electric resistance of the motor,

ω is an angular velocity of a rotor of the motor,

Φ is a number of magnetic cross fluxes of a permanent magnet of the motor,

j_d is a d-axis state quantity of said controller,

j_q is a q-axis state quantity of said controller, and

ω_d is a coefficient
